

1. What is an Application?

An application is a piece of code written to solve a particular problem. Whenever there is a real-world problem, we write a piece of code to solve that problem. That piece of code is called an application. Different applications are developed to solve different real-world problems.

2. What does solving a problem mean in application development?

Solving a problem means solving a real-world problem by writing a piece of code. Problems like shopping, ticket booking, food ordering, travelling from one place to another, and attending online classes are real-world problems. A piece of code written to solve such problems is called an application.

3. What are the different types of Applications?

Applications are mainly classified into two types: **Standalone Applications** and **Web Applications**. Mobile applications are also available, but they can come under the standalone category or the web category depending on how they are developed.

4. What is a Standalone Application?

A Standalone Application is an application that does not require the internet for its working. It runs only on the system where it is installed. If the application is available on one computer, it works only on that computer.

5. What is a Web Application?

A Web Application is an application that stays on a server and can be accessed through a client using the internet or a network. Any application that resides on a server and is accessed through a browser over the internet is called a Web Application.

6. What is the difference between a Standalone Application and a Web Application?

A Standalone Application does not require the internet and runs only on the local system where it is installed. A Web Application requires a server, a client, and the internet or a network. It can be accessed from anywhere through a browser.

7. What are the requirements of a Web Application?

A Web Application requires three important components:

- Server
- Client

- Internet or Network

Without these three components, a Web Application cannot be accessed by users.

8. Why are Web Applications used for solving real-world problems?

Whenever a real-world problem has to be solved, the application should be a Web Application because users can access it from anywhere through the internet. Applications such as shopping, ticket booking, food ordering, travelling, and online learning are all Web Applications because they are accessible to everyone.

9. What is a Client in Web Application Development?

In Web Application Development, the client is the **browser**. Users open the browser, connect to the internet, and access the application that is running on the server. In this context, client always refers to the browser.

10. How does a Web Application work?

A Web Application stays on a server. The user opens a browser, connects to the internet, and accesses the application. The browser acts as the client and communicates with the server through the internet. The application running on the server provides the required service to the user.

11. Why is an online shopping application considered a Web Application?

An online shopping application solves the real-world problem of shopping without requiring users to visit multiple stores. Users can open the application, browse different products, compare them, and purchase them through the internet. Since the application runs on a server and is accessed through a browser or mobile application, it is a Web Application.

12. Why is understanding an Application important before learning development?

Before building projects, it is important to understand what an application actually is. Once you understand that an application is a piece of code written to solve a real-world problem, it becomes easier to understand why different types of applications exist and how they are developed to solve different kinds of problems.
